

Spling

Ordering without speaking. For anyone the drive-through doesn't hear.

Owner: Laszlo Czako Entity: R-evolv Inc. Date: August 2, 2026 Status: Pre-build

WHAT CHANGED FROM V1

v1 positioned the portable user profile as the moat. That was wrong — cross-assistant memory is a crowded commodity category, and AI reservation booking already ships in production. v2 demotes memory, ordering, and reservations to *table stakes to inherit*, and centres the three capabilities no one was found to be building: language conversion at order composition, the communication profile, and the accuracy ledger.

01 What Spling Is

Spling lets a person order food and book a table through their AI assistant **without using their voice at the point of sale** — composing in their own language, carrying their own communication profile, and delivering clean structured data to the merchant's system in the merchant's language.

It is built for people the spoken channel fails: speech differences, deafness, non-native and non-English speakers, and anyone in a loud car at a low-fidelity speaker. That is a much larger group than "accessibility" usually implies.

POSITIONING

Every voice-AI vendor is trying to hear better through a speaker in traffic. Spling deletes the speaker.

02 The Problem

Human-operated drive-throughs average 80–85% order accuracy. Independent 2026 field testing put traditional drive-throughs at roughly 89% against 83% for AI voice systems — the industry's replacement has not yet beaten what it replaced.

The causes are acoustic and linguistic, not cognitive: road noise, poor speaker hardware, accents, non-native speakers, speech differences, disability. For a person with a speech impediment, the failure is not a 15% error rate — it is routine exclusion from a transaction everyone else completes in ninety seconds.

Removing the acoustic channel removes every failure mode attached to it. This is a different bet from making the channel better, and it is the only bet Spling makes.

03 Competitive Reality — What's Taken, What Isn't

Verified against the public landscape as of August 2, 2026. This section exists to stop us building things that already exist.

CAPABILITY	STATUS	EVIDENCE / CONSEQUENCE
Merchant ordering rail	TAKEN	Square shipped ChatGPT and Claude ordering July 1, 2026 — auto-opt-in, processing fees only. Inherit it.
Restaurant reservations	TAKEN	Multiple OpenTable/Resy MCP servers live in production with encrypted persistent credentials; at least one already carries dietary preferences and visit history. Integrate, do not build.
Cross-assistant memory	TAKEN	PAM open standard, Mem0/OpenMemory, MemoryLake, Supermemory, Zep. Crowded. Conform to PAM rather than invent a format.
Payment rails	TAKEN	Stripe, Square, external checkout. Never touch card data.
Language conversion at order composition	OPEN	No product found composing an order in the user's language and delivering validated structured line items in the merchant's. Translation tools translate text; none of them emit POS-valid orders.
Communication profile	OPEN	No product found treating speech difference as a persistent, portable ordering profile.

Existing memory tools store preferences, not communication needs.

Accuracy ledger

OPEN

Nothing connects what was ordered to what arrived across merchants. Square sees the ticket; the merchant sees the complaint; no one joins them.

THE HONEST SCOPE

Three of the seven rows above are ours. The product is therefore smaller than v1 described — but it is defensible, and it is the part that was the original idea before the concept broadened.

04 Feature Set

A. Language conversion — moat

- Order composed in the user's language, delivered to the POS as validated structured line items in the merchant's language
- Constrained emission: the model may only produce valid POS items, modifiers, and quantities — never free text. This is what makes accuracy possible where voice fails.
- Persistent language profile — set once, applies at every merchant
- Receipts and history stored in the user's language; transaction occurs in the local one
- Travel case: order and pay abroad without reading the local menu

B. Communication profile — moat

- Speech difference, deafness, or non-verbal status recorded once and applied everywhere
- Complete removal of the spoken channel — the order is composed and transmitted as data
- Allergen and dietary constraints enforced at composition, not left to the user to restate
- Caregiver-staged ordering (deferred to Phase 6, but designed for from the schema up)
- Portable and user-owned; exportable in PAM format

C. Accuracy ledger — moat

- Two-way record: what was ordered against what arrived
- User corrections and critique tied to merchant, location, and item
- Per-merchant accuracy scoring accumulating over time
- **The only asset here that compounds.** It is also the sole evidence base for per-order pricing — no ledger, no pricing argument.

D. Table stakes — inherit or integrate, never build

- Menu retrieval and order submission — Square Catalog and Orders API
- Payment — external checkout link via Stripe or Square
- Reservations — integrate an existing OpenTable/Resy MCP server
- Order history and receipts — standard storage, PAM-compatible export
- Pickup code and status readback

E. Deferred

- Native iOS app (Swift) — profile custody, Apple Pay, offline access
- Drive-through geofence detection
- NFC tap-to-complete — requires Apple's paid NFC & Secure Element commercial agreement
- Picture-based menu interface
- Multi-channel queue prioritization

05 Architecture

LAYER	TECHNOLOGY	NOTES
MCP server	TypeScript / Deno on Supabase Edge Functions	The product. Same runtime pattern as Rooted's edge functions.
Transport	Remote HTTPS only	ChatGPT does not accept stdio servers. Hosted endpoint is mandatory.
Auth	OAuth 2.1 + Dynamic Client Registration	Bearer tokens not accepted by ChatGPT. Hard requirement.
Data	Supabase Postgres, RLS-enforced	Communication profile, language profile, history, accuracy ledger.
Composition engine	Deterministic validator + constrained LLM	LLM maps intent to candidate items; deterministic code validates against live POS catalog and rejects anything invalid. Same governance pattern as the Pulse Engine.
Merchant rail	Square Orders + Catalog API	Never scrape menus.

Payment	Stripe / Square payment links	PCI scope stays at zero.
Export	PAM (Portable AI Memory) JSON	Conform to the existing standard rather than inventing one.

Tool surface

get_menu · compose_order · place_order · get_order_status · get_profile · update_profile · get_history · submit_correction · export_profile

06 Build Sequence

One definition of done per phase. No phase starts until the previous one is verified end to end.

PHASE 1 Server skeleton

Remote MCP server with OAuth 2.1 + DCR and one tool, `get_menu`, reading a live Square catalog.

DONE WHEN — Claude and ChatGPT both connect and return a real menu from a real merchant.

PHASE 2 Order lands

`compose_order`, `place_order`, payment link. One local restaurant. Real order, real money, real POS.

DONE WHEN — ten consecutive assistant-placed orders land correctly and are paid.

PHASE 3 Language — the real proof

Language profile plus constrained cross-language composition. Order spoken in a non-English language; validated English line items arrive at the POS.

DONE WHEN — ten consecutive non-English orders land correctly. **This phase, not Phase 2, is the thing that is actually ours.**

PHASE 4 Communication profile

`get_profile` / `update_profile` / `export_profile`. Speech and accessibility needs, allergens, history. PAM-format export.

DONE WHEN — a user with a speech difference completes a full order without speaking at the point of sale.

PHASE 5 Accuracy ledger

`submit_correction`. Receipt and correction tied to merchant, location, item. Accumulation begins.

DONE WHEN — a queryable per-merchant accuracy record exists with real entries.

PHASE 6 Reservations + iOS + context

Integrate an existing reservation MCP. Swift client for profile custody and Apple Pay. Geofenced drive-through context.

DONE WHEN — booking, ordering, and profile all reachable from one assistant conversation.

07 Intellectual Property — Unresolved, Highest Priority

A patent covering assisted ordering for users with speech impediments was reportedly drafted some years ago. Its status materially changes this entire plan and must be established before Phase 1.

- **If filed** — the priority date may be the single most valuable asset in the company, predating the current agentic-commerce wave entirely. Retain counsel immediately and determine whether it is live, lapsed, or abandoned.
- **If drafted but never filed** — assess whether any public disclosure occurred. Prior public disclosure can bar patentability. Determine whether a fresh filing is still available.
- **Either way** — the claims should be read against the Phase 3–5 feature set before any of it is published or demonstrated publicly.

ACTION

Locate the document. Determine filing status. This precedes all engineering work and is not a background task.

08 Open Decisions

1. Profile custody

MCP servers must be remotely reachable over HTTPS; ChatGPT cannot read a profile that lives only on a phone. Ship v1 with the profile in Postgres keyed to OAuth identity, schema designed so a move to encrypted blobs with device-held keys is a migration, not a rewrite.

2. Monetization

The consumer will not add a third subscription. The merchant already gets assistant ordering from Square for processing fees. The only defensible ask is a per-order fee justified by measurable accuracy lift — which requires Phase 5 to exist first. A second possibility worth testing: institutional licensing to disability organizations, health authorities, and settlement services, which have budgets and distribution that consumer channels do not.

3. First merchant

Phase 2 needs exactly one willing local restaurant. Identify it before writing code.

09 Non-Goals

- Competing at the protocol layer with UCP, ACP, or MCP
- Building a payment rail or touching card data
- Scraping merchant websites for menus
- Building a general-purpose cross-assistant memory product
- Building a reservation system
- Merchant-side voice AI or drive-through hardware

10 Principal Risks

RISK	MITIGATION
Commodity encroachment — an existing reservation or memory MCP adds language and accessibility handling	Real and already trending: one reservation MCP carries dietary preferences and visit history today. Speed on Phase 3 matters more than breadth.
Platform absorption	Anthropic or OpenAI could add ordering memory natively. Neither has an incentive to build constrained cross-language POS emission or a cross-merchant accuracy ledger.
Patent status unknown	See Section 07. Resolve before building or publishing.
Connector security	Zero-click exfiltration against MCP connector flows has been demonstrated publicly. This server holds disability data and initiates payments. Auth and input validation are Phase 1 design work, not later cleanup.
Sensitive data class	A communication profile recording disability is health-adjacent personal information under PIPEDA and comparable regimes. Data handling, consent, and retention need to be right from the schema up, not retrofitted.
Scope expansion	The concept broadened five times in one planning session before this revision narrowed it. The phase gates exist to hold that line.
Founder capacity	Rooted v38 is at the gate with blocker A8 unresolved. Phase 1 does not begin until v38 ships.

Competitive findings in Section 03 reflect public information as of August 2, 2026 and should be re-verified before Phase 1 — this landscape moved substantially between January and July 2026. "Open" means no product was found doing this, not that none exists. Protocol requirements should be confirmed against current OpenAI and Anthropic developer documentation at build time. Nothing in Section 07 constitutes legal advice; retain a patent agent or IP lawyer.
